

Sequence-to-Sequence Models

Week 4: The Translation Revolution with Attention

NLP Course 2025

Professional Template Edition

September 29, 2025

Week 4: Journey Through Translation and Attention

- 1 Part 1: Translation Challenge & Motivation
- 2 Part 2: Encoder-Decoder Architecture
- 3 Part 3: The Attention Revolution
- 4 Part 4: Implementation & Applications

Learning Path: From word-by-word replacement to neural translation. Master encoder-decoder architectures, understand the bottleneck problem, and discover how attention revolutionized machine translation.

Part 1: Translation Challenge & Motivation

Why Word-by-Word Translation Fails

The Google Translate Evolution: A Success Story

2006: Statistical MT

- Word/phrase dictionaries
- Counted co-occurrences
- “Reasonable” translations
- Often awkward phrasing

2016: Neural MT Launch

- Seq2Seq with attention
- Human-quality for some pairs
- 60% error reduction
- Revolutionary improvement

Real Example:

Chinese Input: “There is one cat in station”

Old: “In the station is one cat”

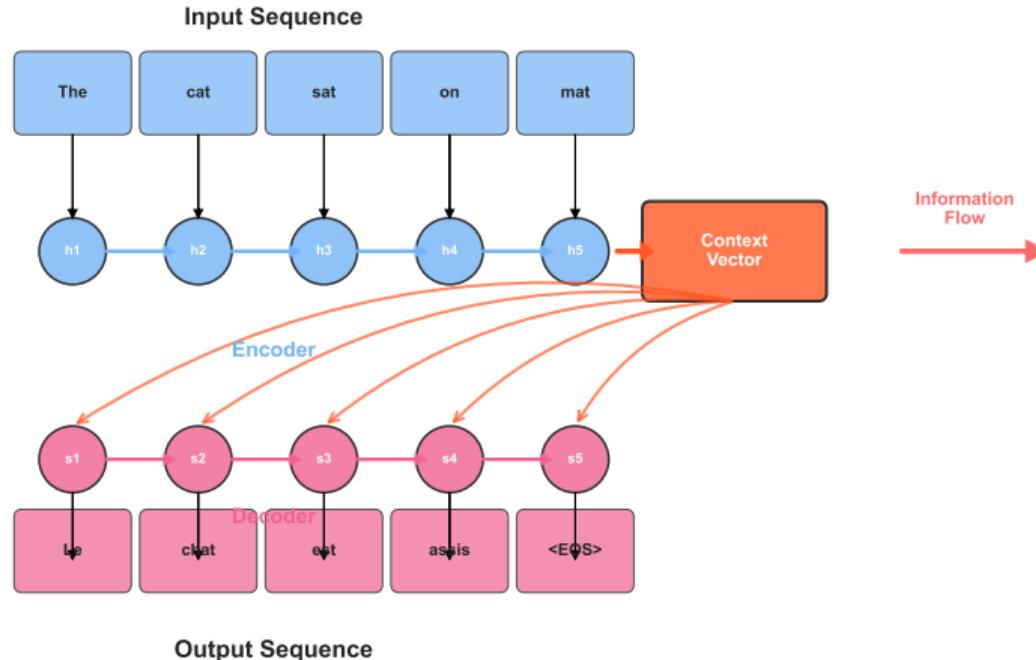

New: “There is a cat at the station”

What changed? Understanding context, not just words

Historical Context: Neural MT reduced translation errors by 60% overnight - the biggest leap in MT history

The Fundamental Problem: Meaning Across Languages

Sequence-to-Sequence Architecture: Encoder-Decoder with Context Vector

Translation is NOT:

Translation IS:

Why Word-by-Word Translation Fails: Concrete Examples

Problem 1: Word Order

- English: "I saw the red house"
- Spanish: "Vi la casa roja"
- Literal: "Saw-I the house red"

Problem 2: Idioms

- English: "It's raining cats and dogs"
- French: "Il pleut des cordes"
- Literal: "It rains ropes"

Problem 3: Context

- "Bank" → "Banque" (financial)
- "Bank" → "Rive" (river)
- Need full sentence to decide

Problem 4: Grammar

- German: Verb at end
- Japanese: Subject optional
- Chinese: No tenses

Conclusion: Languages encode meaning differently - translation needs deep understanding

Language Diversity: Each language has unique ways of expressing ideas

Converting Meaning to Numbers: The Core Challenge

Computers only understand numbers, so:

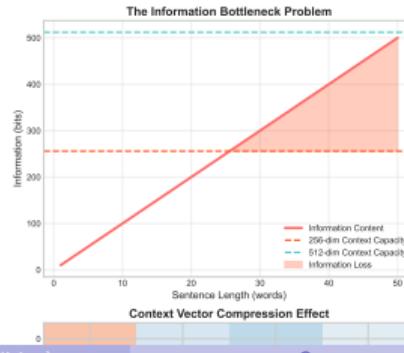

"The cat sat on the mat" → [Numbers] → "Le chat s'est assis sur le tapis"

Step 1: Words to Vectors

- "cat" → [0.2, -0.5, 0.8, ...]
- 100-300 dimensional vectors
- Learned from context (Word2Vec)
- Similar words = nearby vectors

Step 2: Sentence to Vector

- Combine word vectors
- Build "context vector"
- Fixed size (e.g., 256 dims)
- Must capture ALL meaning

The Compression Challenge: Information Bottleneck

Interactive Exercise: Manual Translation Steps

Task: Translate “The black cat sat” to French step-by-step

Your Steps:

1. Read entire English sentence
2. Identify: subject (cat), verb (sat)
3. Recall French words:
 - cat → chat
 - black → noir
 - sat → s'est assis
4. Apply French grammar:
 - Article-Noun-Adjective order
 - Gender agreement (le/la)
5. Generate: “Le chat noir s'est assis”

What You Actually Did:

1. Encoded English to meaning
2. Stored meaning in memory
3. Decoded meaning to French

This is exactly Seq2Seq!

Key Observation:

You didn't translate word-by-word! You understood first, then generated.

Human Insight: We naturally use encoder-decoder approach when translating

Calculating the Bottleneck: A Mathematical Perspective

Information Content:

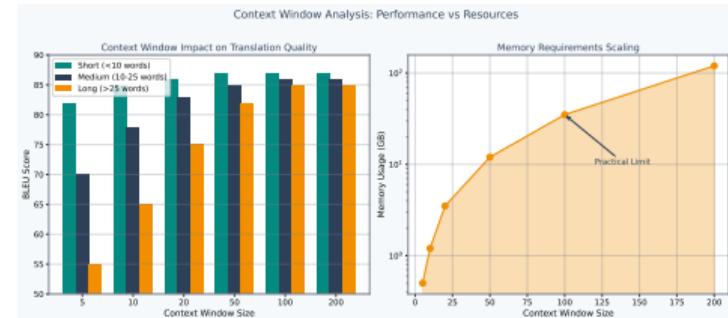

$$\text{Input} = n \times d_{\text{embed}}$$

$$\text{Context} = d_{\text{hidden}}$$

$$\text{Ratio} = \frac{n \times d_{\text{embed}}}{d_{\text{hidden}}} \quad (3)$$

Example Calculation:

- 20 words, 100-dim embeddings
- Input: $20 \times 100 = 2000$ values
- Context: 256 values
- Compression: $\frac{2000}{256} \approx 8 : 1$

The Problem:

Cannot fit 2000 numbers into 256 without loss!

Mathematical Reality: Information theory limits how much we can compress without loss

Part 1 Summary: Understanding the Challenge

What We Learned:

- Translation \neq word replacement
- Languages encode differently
- Need meaning understanding
- Must convert to numbers
- Fixed-size bottleneck problem

Sequence-to-Sequence Architecture

The Challenge:

- Variable input length
- Fixed context size
- Information loss inevitable
- Longer = worse compression

Key Question:
How do we capture all meaning in a fixed-size vector?

Next: The encoder-decoder architecture - a first solution to the translation challenge

Part 2: Encoder-Decoder Architecture

Building Understanding, Then Generating

How humans translate (simplified):

Phase 1: Understanding

1. Read entire source sentence
2. Extract complete meaning
3. Store in “mental representation”
4. Forget specific words
5. Keep abstract meaning

Result: Language-agnostic meaning

Phase 2: Generation

1. Access stored meaning
2. Apply target grammar
3. Choose appropriate words
4. Generate word-by-word
5. Maintain coherence

Result: Natural target sentence

Neural Equivalent: Encoder (understanding) + Decoder (generation) = Seq2Seq

Cognitive Model: Seq2Seq mimics human two-phase translation process

The Encoder: Building Understanding Step-by-Step

Sequence-to-Sequence Architecture: Encoder-Decoder with Context Vector

Encoder's Job:

- Process input sequentially

Processing “The cat sat”:

1. $h_1 = \text{RNN}(\text{"The"}, h_0)$

The Decoder: Generating from Understanding

Decoder's Job:

- Start with context vector c
- Generate one word at a time
- Use previous word + context
- Stop at end token

Generation Process:

$$s_0 = c \text{ (initialize)} \quad (6)$$

$$s_t = \text{RNN}(y_{t-1}, s_{t-1}) \quad (7)$$

$$P(y_t) = \text{softmax}(W s_t) \quad (8)$$

Generating "Le chat noir":

1. Start: $s_0 = c, y_0 = \text{iSTART}_i$
2. Generate "Le": $P(y_1 | c)$
3. Generate "chat": $P(y_2 | y_1, c)$
4. Generate "noir": $P(y_3 | y_{1:2}, c)$
5. Stop: $y_4 = \text{iEND}_i$

Key: Each word depends on context + history

Variable input length

Variable output length

Sequence-to-Sequence Architecture

Complete Seq2Seq Implementation in PyTorch

```
1 import torch
2 import torch.nn as nn
3
4 class Seq2Seq(nn.Module):
5     def __init__(self, src_vocab,
6                  tgt_vocab, embed_dim=256,
7                  hidden_dim=512):
8         super().__init__()
9
9     # Embeddings
10    self.src_embed = nn.Embedding(
11        src_vocab, embed_dim
12    )
13    self.tgt_embed = nn.Embedding(
14        tgt_vocab, embed_dim
15    )
16
17    # Encoder & Decoder
18    self.encoder = nn.LSTM(
19        embed_dim, hidden_dim,
20        batch_first=True
21    )
22    self.decoder = nn.LSTM(
23        embed_dim, hidden_dim,
24        batch_first=True
25    )
26
27    # Output projection
28    self.output = nn.Linear(
29        hidden_dim, tgt_vocab
```

```
1 def forward(self, src, tgt):
2     # Encode
3     src_emb = self.src_embed(src)
4     _, (h, c) = self.encoder(
5         src_emb
6     )
6
7     # Decode
8     tgt_emb = self.tgt_embed(tgt)
9     out, _ = self.decoder(
10        tgt_emb, (h, c)
11    )
12
13     # Project
14     logits = self.output(out)
15
16     return logits
17
18
19 # Usage
20 model = Seq2Seq(
21     src_vocab=10000,
22     tgt_vocab=10000
23 )
24
25 # Training step
26 src = torch.randint(0, 10000,
27                     (32, 20))
28 tgt = torch.randint(0, 10000,
29                     (32, 15))
30 logits = model(src, tgt)
```

Encoding Example: “The black cat sat”

Watch the hidden state evolve:

Step 1: Process “The”

- Input: $x_1 = \text{embed}(\text{"The"}) = [0.1, 0.3, \dots]$
- Hidden: $h_1 = \text{LSTM}(x_1, h_0)$
- Memory: “Determiner seen”

Step 2: Process “black”

- Input: $x_2 = \text{embed}(\text{"black"})$
- Hidden: $h_2 = \text{LSTM}(x_2, h_1)$
- Memory: “Determiner + adjective”

Step 3: Process “cat”

- Input: $x_3 = \text{embed}(\text{"cat"})$
- Hidden: $h_3 = \text{LSTM}(x_3, h_2)$
- Memory: “Black cat (subject)”

Step 4: Process “sat”

- Input: $x_4 = \text{embed}(\text{"sat"})$
- Hidden: $h_4 = \text{LSTM}(x_4, h_3)$
- Memory: “Black cat sat (complete)”

`../figures/hidden_state_evolution.pdf`

Decoding Example: Generating “Le chat noir”

Starting from context c :

Step 1: Generate “Le”

- State: $s_0 = c$
- Input: START_{L} token
- Output: $P(\text{"Le"}) = 0.8$
- Next: $s_1 = \text{LSTM}(\text{"Le"}, s_0)$

Step 2: Generate “chat”

- State: s_1 (knows “Le”)
- Input: “Le”
- Output: $P(\text{"chat"}) = 0.7$
- Next: $s_2 = \text{LSTM}(\text{"chat"}, s_1)$

Step 3: Generate “noir”

- State: s_2 (knows “Le chat”)
- Input: “chat”
- Output: $P(\text{"noir"}) = 0.6$
- Next: $s_3 = \text{LSTM}(\text{"noir"}, s_2)$

Probability Distribution:

At each step, model outputs:

`..//figures/generation_probability.pdf`

Quiz Checkpoint: Understanding Seq2Seq

Questions:

Q1: What is the context vector?

- a) Average of word embeddings
- b) Final encoder hidden state
- c) Sum of all hidden states
- d) Random initialization

Q2: Why use two separate networks?

- a) Faster training
- b) Different tasks (read vs write)
- c) More parameters
- d) Requirement of RNNs

Q3: Teacher forcing means:

- a) Using true targets during training
- b) Forcing convergence
- c) Teaching the teacher

Answers:

A1: b) Final encoder hidden state

- Contains full sentence understanding
- Fixed-size representation
- Passed to decoder

A2: b) Different tasks

- Encoder: comprehension
- Decoder: generation
- Different objectives

A3: a) Using true targets

- Feed correct previous word
- Speeds up training
- Avoids error accumulation

Part 2 Summary: The Encoder-Decoder Solution

Architecture Components:

- Encoder RNN: reads input
- Context vector: compressed meaning
- Decoder RNN: generates output
- End-to-end training

Strengths:

- Variable input/output length
- End-to-end learning
- No alignment needed
- Works for any language pair

Key Equations:

$$c = \text{Encoder}(x_{1:n}) \quad (9)$$

$$y_t = \text{Decoder}(c, y_{<t}) \quad (10)$$

Weakness:

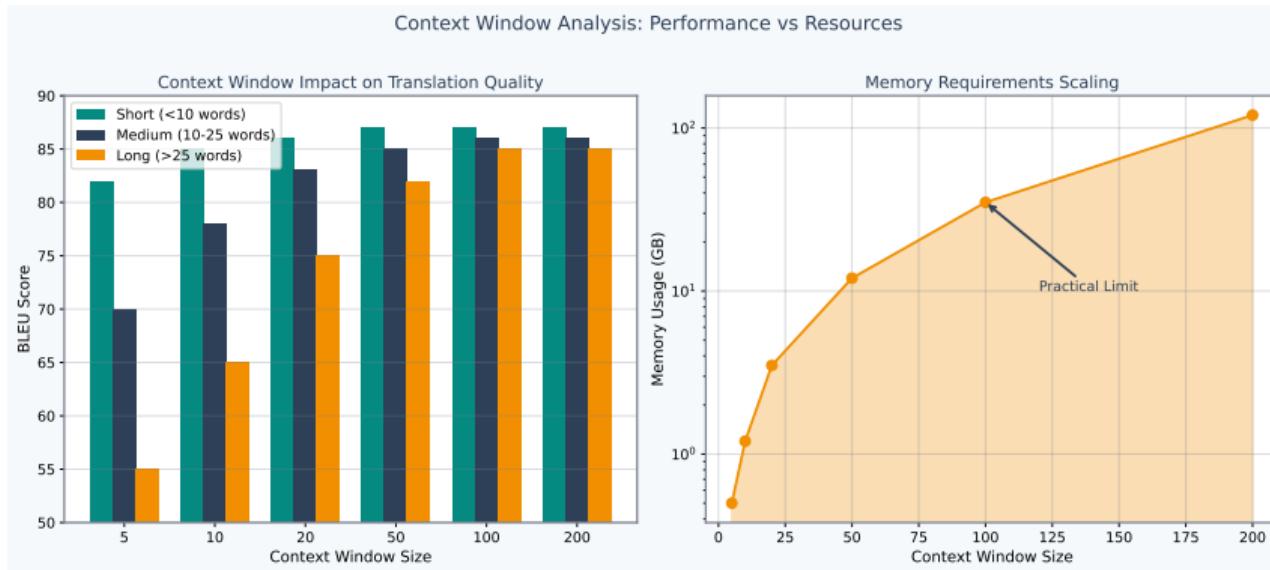

Fixed-size bottleneck!

Part 3: The Attention Revolution

Looking Back at All Hidden States

The Bottleneck Problem: Why Seq2Seq Fails on Long Sentences

Performance Degradation:

- 10 words: BLEU = 35
- 20 words: BLEU = 25
- 30 words: BLEU = 15
- 40+ words: BLEU < 10

What's Lost:

- Early words forgotten
- Specific details blurred
- Word positions unclear
- Grammatical structure

Human Translation: The Attention Analogy

How do humans really translate long sentences?

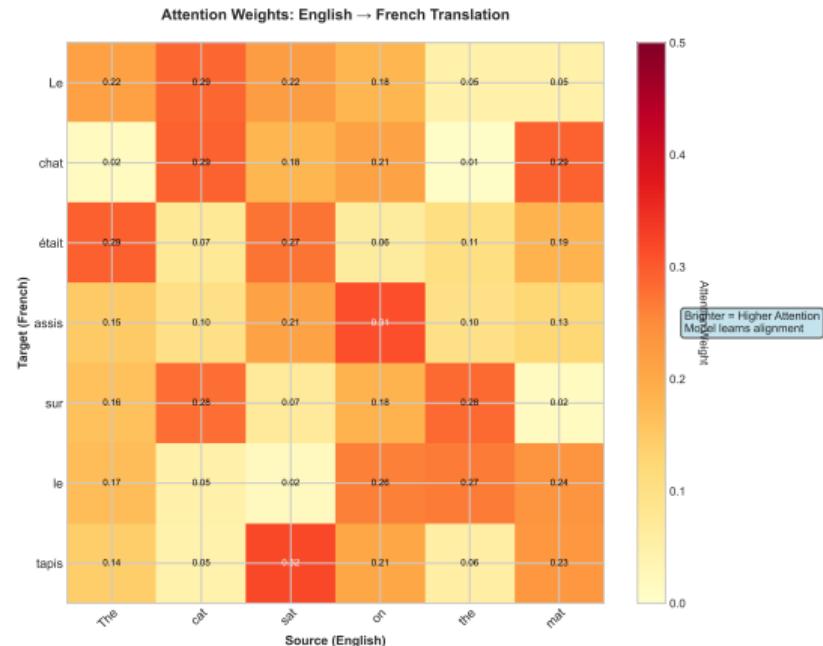

Translating Word by Word:

"The black cat that I saw yesterday sat"

When translating "sat":

1. Look back at "cat" (subject)
2. Check tense markers
3. Verify agreement
4. Generate appropriate form

Key: We don't memorize everything! We look back as needed.

Attention Idea:

Computing attention weights:

Step 1: Score How relevant is each encoder state?

$$e_{ti} = \text{score}(s_{t-1}, h_i)$$

Common scoring functions:

- Dot: $s_{t-1} \cdot h_i$
- General: $s_{t-1} W h_i$
- Concat: $v \tanh(W[s_{t-1}; h_i])$

Step 2: Normalize Convert scores to probabilities:

$$\alpha_{ti} = \frac{\exp(e_{ti})}{\sum_j \exp(e_{tj})}$$

Step 3: Weighted Sum Compute dynamic context:

$$c_t = \sum_{i=1}^n \alpha_{ti} h_i$$

Intuition:

- s_{t-1} = Query (what I need)
- h_i = Key (what's available)
- h_i = Value (what to use)
- α_{ti} = Relevance weight

This is the foundation of all modern transformers!

Mathematical Foundation: Attention as weighted information retrieval

Visualizing Attention: What the Model Focuses On

Implementing Attention in PyTorch

```
1 class Attention(nn.Module):
2     def __init__(self, hidden_dim):
3         super().__init__()
4         self.attn = nn.Linear(
5             hidden_dim * 2, hidden_dim
6         )
7         self.v = nn.Linear(
8             hidden_dim, 1, bias=False
9         )
10
11     def forward(self, hidden,
12                 encoder_outputs):
13         # hidden: [1, batch, hidden]
14         # encoder_outputs:
15         #   [batch, seq_len, hidden]
16
17         batch = encoder_outputs.size(0)
18         seq_len = encoder_outputs.size(1)
19
20         # Repeat decoder hidden
21         hidden = hidden.squeeze(0)
22         hidden = hidden.unsqueeze(1)
23         hidden = hidden.repeat(
24             1, seq_len, 1
25         )
26
27         # Concatenate and score
28         energy = torch.tanh(self.attn(
29             torch.cat((hidden,
30                       encoder_outputs), 2)
31
32         # Compute attention weights
33         attention = self.v(energy)
34         attention = attention.squeeze(2)
35
36         # Softmax over seq_len
37         weights = F.softmax(
38             attention, dim=1
39         )
40
41         # Weighted sum
42         context = torch.bmm(
43             weights.unsqueeze(1),
44             encoder_outputs
45         )
46
47         return context, weights
48
49     # Usage in decoder
50     attn = Attention(hidden_dim=512)
51
52     # Each decoding step
53     context, weights = attn(
54         decoder_hidden,
55         encoder_outputs
56     )
57
58     # Combine context with input
59     decoder_input = torch.cat(
60         (embedded, context), dim=2
61     )
```

Interactive Exercise: Calculate Attention Weights

Task: Compute attention for generating “noir” (black)

Given decoder state s_2 after generating “Le chat”:

Encoder states:

- h_1 : “The” = [0.1, 0.2]
- h_2 : “black” = [0.8, 0.9]
- h_3 : “cat” = [0.5, 0.4]
- h_4 : “sat” = [0.3, 0.1]

Decoder query:

- s_2 = [0.7, 0.8]

Your calculations:

1. Scores (dot product):

- $e_1 = s_2 \cdot h_1 = \underline{\hspace{2cm}}$
- $e_2 = s_2 \cdot h_2 = \underline{\hspace{2cm}}$
- $e_3 = s_2 \cdot h_3 = \underline{\hspace{2cm}}$
- $e_4 = s_2 \cdot h_4 = \underline{\hspace{2cm}}$

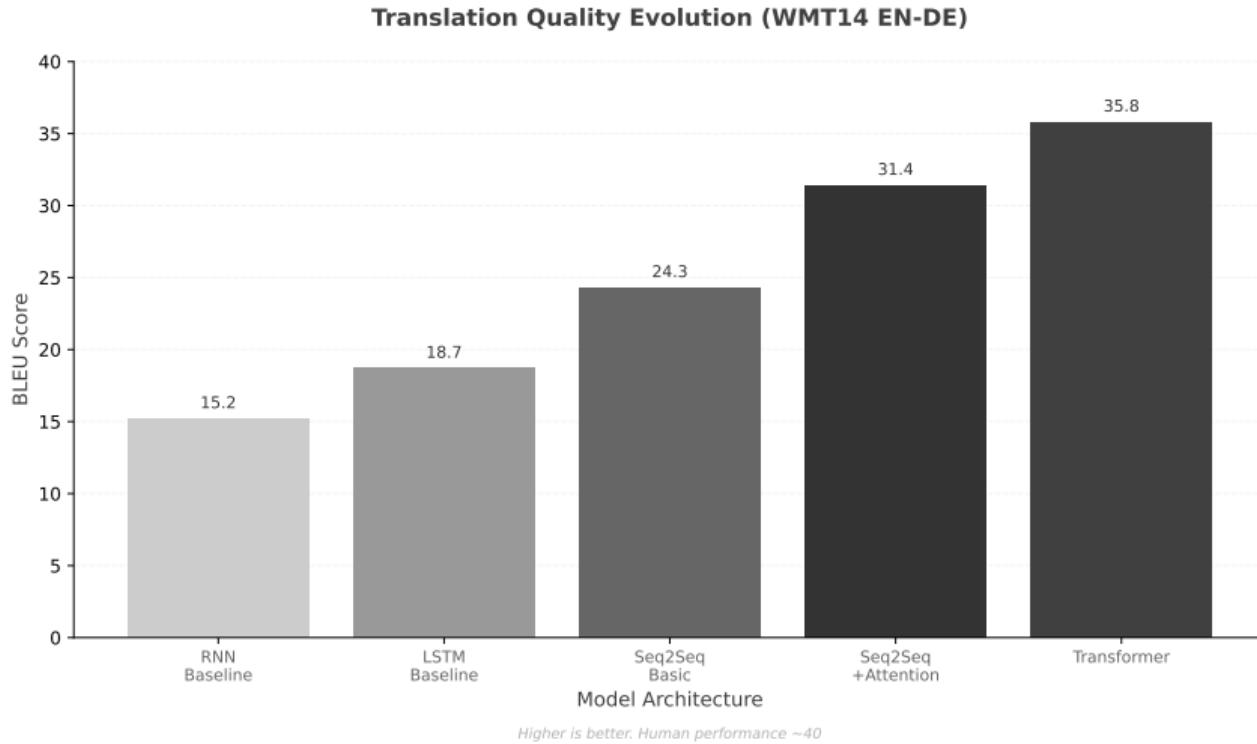

2. Softmax weights:

- $\alpha_2 = \underline{\hspace{2cm}}$ (highest!)

3. Context: weighted sum

Hands-On: Computing attention manually builds intuition for the mechanism

Impact of Attention: Dramatic Improvements

BLEU Score Improvements:

Why It Works:

Part 3 Summary: The Attention Revolution

The Innovation:

- Dynamic context vectors
- Look at all encoder states
- Weighted by relevance
- Different for each word

Mathematical Core:

$$\alpha_{ti} = \text{softmax}(\text{score}(s_t, h_i)) \quad (11)$$

$$c_t = \sum_i \alpha_{ti} h_i \quad (12)$$

Impact:

Attention mechanism became foundation of all modern NLP

Historical Significance: Attention paper (2014) revolutionized entire field

Part 4: Implementation & Applications

From Research to Production

Complete Seq2Seq with Attention

```
1  class AttentionSeq2Seq(nn.Module):
2      def __init__(self, src_vocab,
3                  tgt_vocab, dim=512):
4          super().__init__()
5
5          # Components
6          self.encoder = Encoder(
7              src_vocab, dim
8          )
9          self.decoder = DecoderWithAttn(
10             tgt_vocab, dim
11         )
12          self.attention = Attention(dim)
13
14      def forward(self, src, tgt,
15                  teacher_forcing=0.5):
16          # Encode all at once
17          enc_out, (h, c) = self.encoder(src)
18
19          batch = src.size(0)
20          max_len = tgt.size(1)
21          vocab = self.decoder.vocab_size
22
23          # Store outputs
24          outputs = torch.zeros(
25              batch, max_len, vocab
26          )
27
28          # First input
29          input = tgt[:, 0]
30
31          for t in range(1, max_len):
32              # Attention context
33              context, weights =
34                  self.attention(
35                      h, enc_out
36                  )
37
38              # Decode one step
39              output, (h, c) =
40                  self.decoder(
41                      input, (h, c),
42                      context
43                  )
44
45              outputs[:, t] = output
46
47              # Teacher forcing
48              use_teacher = random.random() < teacher_forcing
49
50              if use_teacher:
51                  input = tgt[:, t]
52              else:
53                  input = output.argmax(1)
54
55      return outputs
```

Training Dynamics: Learning to Translate

Training Monitoring Dashboard

Beam Search: Better Decoding Strategy

Greedy vs Beam Search:

- Greedy: Pick best at each step
- Beam: Keep top-k hypotheses
- Explore multiple paths
- Better final translations

Example with beam=3:

Step 1: "Le", "Un", "Les"

Step 2:

- "Le chat", "Le chien"
- "Un chat", "Les chats"

Step 3: Keep expanding top-3

Seq2Seq Models: Modern Applications Ecosystem (2024)

Lab Preview: Build Your Own Translator

Week 4 Lab: English-French Neural Machine Translation

What You'll Build:

1. Load parallel corpus
2. Tokenize and preprocess
3. Implement encoder-decoder
4. Add attention mechanism
5. Train on GPU
6. Visualize attention weights
7. Compare with/without attention

Dataset:

- 10,000 sentence pairs
- English → French
- Average 15 words/sentence

Expected Results:

Bonus Challenges:

- Multi-head attention
- Bidirectional encoder
- Coverage mechanism
- Back-translation

Interactive Debugging: Common Training Issues

Your model isn't learning. Debug these issues:

Issue 1: Attention all uniform

Symptoms:

- All weights $\approx 1/n$
- Poor translation quality
- Not improving

Your fix: _____

Hint: Check score function

Common Fixes:

Fix 1: Initialize properly

- Use Xavier initialization
- Scale attention scores
- Add small epsilon to softmax

Issue 2: Mode collapse

Symptoms:

- Always generates "the the the"
- Loss plateaus high

Fix 2: Teacher forcing

- Start with 100% teacher forcing
- Gradually reduce ratio
- Scheduled sampling

Debug systematically!

Debugging Skills: Most issues come from initialization or training schedule

Performance Comparison: Evolution of Translation

The Bridge to Transformers (Week 5 Preview)

From Seq2Seq+Attention to Transformers:

What We Keep:

- Attention mechanism
- Query-Key-Value
- Position awareness
- Encoder-decoder structure

What We Add:

- Self-attention
- Multi-head attention
- Position encodings
- Layer normalization
- Parallel processing

What We Remove:

- RNN/LSTM cells
- Sequential processing
- Recurrent connections
- Hidden state passing

Part 1: Challenge

- Translation \neq word replacement
- Need meaning understanding
- Information bottleneck problem

Part 2: Seq2Seq

- Encoder-decoder architecture
- Fixed context vector
- Works but limited by bottleneck

Part 3: Attention

- Dynamic context vectors
- Look at all encoder states
- Massive performance improvement

Part 4: Applications

- Complete implementation
- Beam search decoding
- Powers modern translation
- Foundation for transformers

Key Takeaways:

1. Context vectors compress meaning
2. Attention removes bottleneck
3. Foundation of modern NLP
4. Bridge to transformers

Next Week: Transformers - Attention Without RNNs!

Achievement Unlocked: You understand the foundation of all modern language AI!
